

## UNIT - 3

### Deadlocks

Imp

\* **Deadlock :-** A deadlock is a situation in which some process wait for each other actions indefinitely. It can arise in a synchronisation situation.

Example- When process wait for the other process to send them message or to release resources that they need.

- **Definition of deadlock -** Deadlock means a lock having no keys.  
A set of process is in deadlock if each of them wait for an event that can be cause only by process in the set. Thus each process wait for an event that cannot occur. This situation arises if the following conditions are satisfied-

- 1- Process  $P_i$  in a set of processes  $\Delta$  is blocked on some event  $E_j$ .
- 2- Event  $E_j$  can be cause only by actions of other process in  $\Delta$ .

Each process  $P_i$  in  $\Delta$  must satisfy above two conditions for  $\Delta$  to be in deadlock

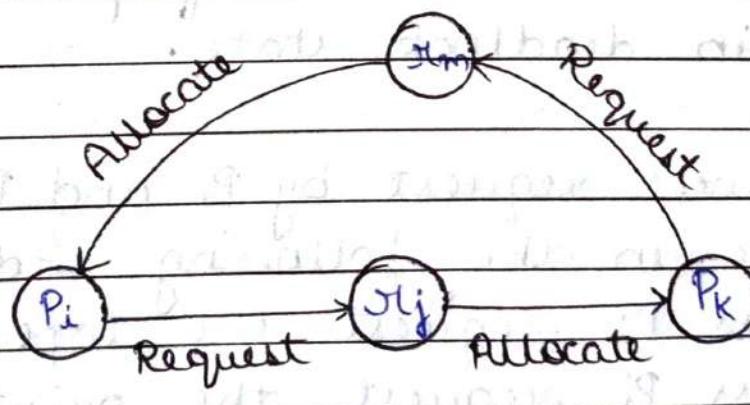

state.

- \* Deadlocks in Resource allocation :- Three events concerned the resource allocation can occur in a system.

1. Request for a resource.
2. Allocation for a resource.
3. Release of a resource.

A request event occurs when process  $P_i$  makes a request for a resource  $R_j$ . If  $R_j$  is currently allocated to some process  $P_k$ , process  $P_i$  gets locked on an allocation event for  $R_j$ . In effect  $P_i$  is waiting for  $P_k$  to release  $R_j$ .

A release event by  $P_k$  free resource  $R_j$ . It can cause the allocation event for which  $P_i$  is waiting. Process  $P_i$  will face an indefinite wait if  $P_k$ 's release of  $R_j$  is indefinitely delayed.

Deadlock

There may be another resource  $R_m$  which is allocated to the process  $P_i$  and process  $P_k$  request for it to accomplish its task then same will occur that is until  $P_i$  release the resource  $R_m$ .  $P_k$  can't complete its task so both process  $P_i$  and  $P_k$  are locked. No (process) task is perform in the system.

example A system contains one tape and one printer and two process  $P_i$  and  $P_j$  that use these resource as follow -

Process i	Process j
Request tape	Request Printer
Request printer	Request tape
Use tape and printer	Use tape and printer
Release tape	Release Printer
Release Printer	Release tape

Show that the set of process  $P_i, P_j$  is in deadlock state.

solution: Resource request by  $P_i$  and  $P_j$  take place in the following order -

- 1- Process  $P_i$  request the tape.
- 2- Process  $P_j$  request the printer.
- 3- Process  $P_i$  request the printer

4- Process P<sub>j</sub> request the tape.

The first two requests are granted immediately because a tape and printer exist in the printer. Now process P<sub>i</sub> hold the tape and P<sub>j</sub> hold the printer. When P<sub>i</sub> ask for the printer it is blocked until P<sub>j</sub> release the printer.

Similarly P<sub>j</sub> is locked until P<sub>i</sub> release the tape. So the set of process P<sub>i</sub>, P<sub>j</sub> is in deadlock state.

\* Necessary conditions for a resource deadlock -

1. Mutual exclusion (Non-shareable resources) - Resources cannot be shared a process need exclusive access to a resource. If another process request that resource, it is block until the resource is release by the first process.

2. Hold and wait - A process continue to hold the resources allocated to it while waiting for other resources.

3. No preemption - OS preempt a resource from one process in order to allocate it to another process. A resource can be

release after that process completed its task.

4. Circular wait - A circular chain of hold and wait conditions exist in the system. A set of waiting processes  $P_0, P_1, \dots, P_n$  must exist in the system such that  $P_0$  is waiting for the resource held by  $P_1$ ,  $P_1$  is waiting for the resource held by  $P_2$  and so on.  $P_{n-1}$  is waiting for the resource held by  $P_n$  and  $P_n$  is waiting for the resource held by  $P_0$ .

#### \* Handling deadlocks :-

There are 3 fundamental approach used in deadlock handling. Each approach has different implications for user process and for the operating system.

- 1- Deadlock Prevention - The kernel uses a resource allocation policy that ensure that the four conditions for resource deadlock do not arise simultaneously. This approach makes deadlock impossible.

- 2- Deadlock Avoidance - The kernel analyzes

allocation state to determine whether granting a resource request might lead to be a deadlock later. Only request, that cannot lead to a deadlock are granted, others are kept pending until they can be granted.

3- Deadlock detection and resolution - The kernel analyze the resource state to check whether a deadlock exist, if so it abort some process and allocates the resources held by them to other process. So that the deadlock classes to exist.

#### \* Deadlock Avoidance :-

Given a prior information about the maximum number of resources of each type that may be requested for each process. It is possible to construct an algorithm that ensure that the system will never enter a deadlock state. This approach is called as deadlock avoidance.

- Safe state - A state is safe if the system can allocate resources to each process in some order and avoid deadlock.

Formally a system is said to be in safe state only if there exist a safe sequence.

- Unsafe state - If no such sequence exist then the system state is said to be unsafe.

A safe state is not a deadlock state conversely, a deadlock state is an unsafe state.

UNSAFE STATE
--------------

Deadlock
----------

SAFE
------

Fig:- Safe, Unsafe, Deadlock State

Example - Consider a system with 12 tape driver and 3 process as -

Process	Maximum needs	Current need	Available
P <sub>0</sub>	10	5	12
P <sub>1</sub>	4	2	
P <sub>2</sub>	9	3	

Out of 12 available tape drivers suppose at time t, process P<sub>0</sub> is holding 5 tapes, P<sub>1</sub> hold 2 tapes, P<sub>2</sub> hold 3 tapes and 3 tape drivers are free. Whether this system is in deadlock state or not.

\* Banker's algorithm :- The resource allocation graph algorithm is not applicable to a resource allocation system with multiple instance of each resource type, the deadlock avoidance scheme that we describe next is applicable to such a system. But is less efficient than resource allocation graph scheme. This algorithm is commonly known as Banker's algorithm.

Several data structures are required to implement the Banker algorithm. Let  $n$  be the number of process in the system and  $m$  be the number of resource type. We need the following data structures -

1. Available - A vector of length  $M$  indicates the number of available resources of each type. If  $\text{available}[j] = k$  instance of resource type  $r_j$  are available. It is a one-dimensional array of length  $m$ .
2. Max - It is a 2-dimensional array (matrix) of length  $n \times m$  that defines the maximum demand of each process in a system. If  $\text{max}[i,j] = k$  then

process  $P_i$  may request at most  $k$  instance of resource type  $R_j$ .

3- Allocation - It is also a 2-D array of length  $n \times m$  that defines the number of resources of each type currently allocated to each process.

If allocation  $[i, j] = k$  then process  $P_i$  currently allocate  $k$  instance of resource type  $R_j$ .

4: Need - If need  $[i, j] = k$  then process  $P_i$  may need  $k$  more instance of resource type  $R_j$  to complete its task.

$$\text{Need}[i, j] = \text{Max}[i, j] - \text{Allocation}[i, j]$$

#### \* Safety Algorithm :-

The algorithm for finding out whether or not a system is in a safe state can be describe as follow -

1. Let work n finish by vector  $m$  and  $n$ .

Initialize work = available

finish  $[i] = \text{false}$ ;

2. Finish an  $i$  such that both -

(i)  $\text{finish}[i] = \text{false}$

(ii)  $\text{Need} \leq \text{work}$

if no such  $i$  exist, go to step 4.

3.  $\text{Work} = \text{Work} + \text{Allocation}$

$\text{finish}[i] = \text{true}$

go to step 2

4. If  $\text{finish}[i] = \text{true}$  for all  $i$ ,  
then the system is in safe state.

\*

### Resource request algorithm

Let  $\text{request}_i$  be the request vector  
for process  $P_i$ . If  $\text{request}_i[R_j] = k$   
then process  $P_i$  wants  $k$  instance of  
resource type  $R_j$ . When a request for  
resources is made by process  $P_i$ , the  
following actions are taken :

(1) If  $\text{Request}_i \leq \text{Need}_i$ ,

    go to step (2); otherwise,  
    raise an error condition, since the  
    process has exceeded its maximum  
    claim.

(2) If  $\text{Request}_i \leq \text{Available}$ ,

    go to step (3); otherwise,  
     $P_i$  must wait, since the resources are  
    not available.

(3) Have the system pretend to have

allocated the requested resources to process  $P_i$  by modifying the state as follow:

$$\text{Available} = \text{Available} - \text{Request}_i$$

$$\text{Allocation}_i = \text{Allocation}_i + \text{Request}_i$$

$$\text{Need}_i = \text{Need}_i - \text{Request}_i$$

If the resulting resource-allocation state is safe, the transaction is completed and process  $P_i$  is allocated its resources. However, if the new state is unsafe, then  $P_i$  must wait for  $\text{Request}_i$  and the old resource-allocation state is restored.

Example:- Consider a system with 5 processes  $P_0, P_1, P_2, P_3, P_4$  and 3 resources types A,B,C. Resource type A has 10 instance, B has 5 instance and type C has 7 instance. Suppose at time t<sub>0</sub> following snapshot of the system has been taken -

Process	Allocation	Max	Available
			A B C
$P_0$	0 1 0	7 5 3	3 3 2
$P_1$	2 0 0	3 2 2	
$P_2$	3 0 2	9 0 2	
$P_3$	1 2 1	2 2 2	
$P_4$	0 0 2	4 3 3	

- (i) What will be the content of need matrix?
- (ii) Is the system in safe state? If yes, what is the safe sequence.
- (iii) If request  $(3,3,0)$  by process  $P_4$  arrives, what will happen if process  $P_4$  requires 1 additional instance of resource type A and 2 instances of resource type C.
- (iv) If request  $(3,3,0)$  by process  $P_4$  arrives in the state defined by (iii), can it be granted immediately?
- (v) If a request  $(0,2,0)$  by process  $P_6$  arrives then check whether it is granted or not?

Solution: (i) Content of need matrix -

$$\text{Need} = \text{Max} - \text{Allocation}$$

$$= \begin{bmatrix} 7 & 4 & 3 \\ 1 & 2 & 2 \\ 6 & 0 & 0 \\ 0 & 1 & 1 \\ 4 & 3 & 1 \end{bmatrix}$$

- (ii) Applying safety algorithm on the given system for  $P_i$  if  $\text{Need} < \text{Available}$  then  $P_i$  is in safe sequence.

$\text{Available}_i = \text{Available} + \text{Allocation}$

So for  $P_0$

( $i=0$ )  $\text{Need}_0 \rightarrow 7, 4, 3$

$\text{Available} \rightarrow 3, 3, 2$

Condition is false.

So  $P_0$  must wait.

for  $P_1$

( $i=1$ )  $\text{Need}_1 \rightarrow 1, 2, 2$

$\text{Available} \rightarrow 3, 3, 2$

( $\text{Need} < \text{Available}$ )

$P_1$  will be kept in safe sequence.

Now available will be updated as -

$\text{Available} = \text{Available} + \text{Allocation}$

$= 3, 3, 2 + 2, 0, 0$

$= 5, 3, 2$

for  $P_2$

( $i=2$ )  $\text{Need}_2 \rightarrow 6, 0, 0$

$\text{Available} \rightarrow 5, 3, 2$

Condition is false and  $P_2$  must wait.

for  $P_3$

( $i=3$ )  $\text{Need}_3 \rightarrow 0, 1, 1$

$\text{Available} \rightarrow 5, 3, 2$

Now,  $\text{Available} = 5, 3, 2 + 2, 1, 1$

$= 7, 4, 3$

for  $P_4$

( $i=4$ )  $\text{Need}_4 \rightarrow 4, 3, 1$

$\text{Available} \rightarrow 7, 4, 3$

$\text{Need} < \text{Available}$

$$\text{Now Available} = 7, 4, 3 + 0, 0, 2 \\ = 7, 4, 5$$

Now we have two process  $P_0$  and  $P_2$  in waiting state. As current available either  $P_0$  or  $P_2$  is kept in safe sequence.

Firstly we take  $P_2$  whose need = 6, 0, 0

$$\text{Available} \rightarrow 7, 4, 5$$

$$\text{Need}_2 \leq \text{Available}$$

So  $P_2$  now comes in safe state.

$$\text{Available} = 7, 4, 5 + 3, 0, 2 \\ = 10, 4, 7$$

Next,  $P_0$  whose Need  $\rightarrow 7, 4, 3$  and

$$\text{Available} \rightarrow 10, 4, 7$$

$P_0$  now comes in safe state.

$$\text{and Available} = 10, 4, 7 + 0, 1, 0 \\ = 10, 5, 7$$

So the safe sequence is -

$$\langle P_1, P_3, P_4, P_2, P_0 \rangle$$

(iii) Since  $P_1$  request some additional instances of resources such that

$$\text{Request}_1(1, 0, 2)$$

To decide whether this request is immediately granted as we first check that  $\text{Request} \leq \text{Available}$  which hold true. So the request may be granted.

To confirm that this request is granted we check the new state by applying safety algorithm that our system is in safe state or not.

If the new state is in safe state then only this request is granted otherwise not.

To define the new state of the system because of the arrival of request  $P_1$ . We follow the resource request algorithm which result as-

Process	Allocation	Need	Available
	A B C	A B C	A B C
$P_0$	0 1 0	7 4 3	2 3 0
$P_1$	3 0 2	0 2 0	
$P_2$	3 0 2	6 0 0	
$P_3$	2 1 1	0 1 1	
$P_4$	0 0 2	4 3 1	

We must determine whether this new system state is safe. We again execute a safety algorithm and find the safe sequence as  $\langle P_1, P_3, P_4, P_2, P_0 \rangle$  which satisfy our safety requirements hence we can immediately grant the request for process  $P_1$ .

- (iv) The request for (3 3 0) by  $P_1$  cannot be granted because Request<sub>1</sub> = 3 3 0  
Available = 2 3 0

In this situation the condition is false. So it is not granted since resource are not available.

(v) The request for (020) by process P<sub>0</sub>.

$$\text{Request} = 020$$

$$\text{Available} = 230$$

So the condition is true and the request may be granted.

If it is granted then the new state of the system is define as-

$$\begin{aligned}\text{Available} &= \text{Available} - \text{Request} \\ &= 230 - 020 \\ &= 210\end{aligned}$$

$$\begin{aligned}\text{Allocation} &= \text{Allocation} + \text{Request} \\ &= 010 + 020 \\ &= 030\end{aligned}$$

$$\begin{aligned}\text{Need} &= \text{Need} - \text{Request} \\ &= 743 - 020 \\ &= 723\end{aligned}$$

Process	Allocation	Need	Available
	A B C	A B C	A B C
P <sub>0</sub>	030	723	210
P <sub>1</sub>	302	020	
P <sub>2</sub>	302	600	
P <sub>3</sub>	211	011	
P <sub>4</sub>	002	431	

Ques Consider a system with 5 process  $P_0$ --- $P_4$ . and 3 resources types A, B and C. Resource type A has 7 instance, B has 2 and C has 6 instance. Suppose at time t we have following state -

Process	Allocation			Request			Available		
	A	B	C	A	B	C	A	B	C
$P_0$	0	1	0	0	0	0	0	0	0
$P_1$	2	0	0	2	0	2			
$P_2$	3	0	3	0	0	0			
$P_3$	2	1	1	1	0	0			
$P_4$	0	0	2	0	0	2			

- (i) Is the given system is in deadlock state?
- (ii) Suppose  $P_2$  makes an additional request (001). What will be the effect of this request to the system?

Sol:- (i) For  $P_0 \Rightarrow$  Request = 000  
Available = 000

Condition is true

$$\begin{aligned} \text{Now available} &= \text{Available} + \text{Allocation} \\ &= 000 + 010 \\ &= 010 \end{aligned}$$

for  $P_1 \Rightarrow$  Request = 202

Available = 010

(Request > Available)

Condition is false, so  $P_1$  must wait.

for  $P_2 \Rightarrow$  Request<sub>2</sub> = 000  
Available = 010

Condition is true.

$$\begin{aligned} \text{Now available} &= 010 + 303 \\ &= 313 \end{aligned}$$

for  $P_3 \Rightarrow$  Request<sub>3</sub> = 100  
Available = 313

Condition is true.

$$\begin{aligned} \text{Now available} &= 313 + 211 \\ &= 524 \end{aligned}$$

for  $P_4 \Rightarrow$  Request<sub>4</sub> = 002  
Available = 524

Condition is true.

$$\begin{aligned} \text{Now available} &= 524 + 002 \\ &= 526 \end{aligned}$$

Now for the waiting process  $P_1 \Rightarrow$

Request<sub>1</sub> = 200

Available = 526

Condition is true.

So  $P_1$  comes in safe state.

$$\begin{aligned} \text{Now available} &= 526 + 200 \\ &= 726 \end{aligned}$$

(ii) Since  $P_2$  request some additional instance of resources such that

Request<sub>2</sub> = 001

Available = 726

Request < Available

So the request may be granted.

The new state of the system will be -

Process	Allocation			Available
	A	B	C	
P <sub>0</sub>	010	000	725	
P <sub>1</sub>	200	202		
P <sub>2</sub>	304	001		
P <sub>3</sub>	211	100		
P <sub>4</sub>	002	002		

## \* Deadlock resolution or recovery from deadlock :-

When a detection algorithm determines that a deadlock exist, several alternatives approach can be implemented. One possibility is to inform the operator that a deadlock has occur and to let the operator deal with the deadlock manually. The other possibility is to let the system to recover from the deadlock automatically. There are two options for breaking a deadlock -

- 1- Terminate some process  $P_j$  which is a subset of  $\Delta$  to free the resource required by  $P_i$ .
- 2- Add new unit of resources requested by  $P_i$  or preempt some resources from one or more of the deadlock process.
